Paper II · Unit III · Topic 4 — Telangana Agriculture, Irrigation, Industry, Population and Tribal Development

Status: integrated working edition; NOT academically ready or independently approved. Existing legacy PDF is preserved. This editable master combines the existing original narrative, the previously separate six-section repair, original model answers, 25 new explained practice MCQs, and four additional structured mains answers. No question below is represented as an authenticated official PYQ. A synchronized CI-rendered working PDF is now published; this does NOT mean academic R1–R8 approval. The dedicated Topic 4 renderer is being used to correct its footer, and full post-render accessibility and source checks remain open.

Official syllabus — local transcription; original clause-by-clause recheck pending

Agriculture—rainfed/dryland agriculture, drought-prone areas and mitigation; irrigation through canals, tanks and wells, groundwater depletion and conservation, Mission Kakatiya; industries—cement, sugar, pharmaceuticals, electronics, tourism, IT, ITIR and SEZs; handicrafts and household industries; road and rail networks; population distribution, growth, density, sex ratio, age and literacy; tribal population, tribal-area problems and development policies.

Detailed coverage rule: every comma-separated clause has its own developed section in the notes and the exam fact/answer materials. Cross-check punctuation against Annexure II of TGPSC Notification 02/2024 before final approval.

Core narrative — existing 15 concepts (requires further depth)

1. Agro-climatic reality: dryland farming is an economic system

Large parts of Telangana depend on the onset, timing and distribution of monsoon rainfall, not merely its annual total. **Rainfed agriculture** derives soil moisture mainly from precipitation, while **dryland farming** refers to crop production under limited moisture and high variability, sometimes with protective irrigation. They overlap but are not perfect synonyms. Farmers choose sowing dates, varieties, intercropping and livestock combinations in response to rainfall risk. A rainfall failure after germination differs in consequence from a late onset before sowing. Farmers with small plots, insecure tenancy or poor access to crop credit carry disproportionately high risk. Policy should therefore differentiate seed insurance, weather forecasts, soil-moisture techniques and emergency irrigation rather than announce a single universal drought solution.

Rainfall is an input; crop-available water is the constraint

A farm may receive a reasonable seasonal rainfall total yet experience moisture stress if rain arrives in a few intense events. Runoff, infiltration, soil depth, evaporative demand and the interval between showers determine how much water remains accessible to roots. Telangana's red soils and deeper black soils should not be assigned one uniform storage capacity: field-level soil profile and drainage matter. A farmer with a shallow soil profile may need a shorter-duration crop even where the mandal rainfall total resembles that of a deeper-soil village. **Analytical sequence:** monsoon timing → infiltration and stored soil moisture → crop-stage demand → yield risk → household cash flow. This is a teaching model, not a measured causal estimate for any district.

A farm decision under uncertainty

Consider an illustrative farmer deciding whether to sow immediately after the first shower. Early sowing can exploit moisture but risks seedling loss if the next rain is delayed; waiting can shorten the growing period. The appropriate response is a locally advised sowing window, soil-moisture assessment and seed choice, not a blanket instruction to delay everywhere. Contour bunds, mulching and intercropping can reduce risk where suitable, but their effectiveness depends on slope, soil and crop. Protective irrigation during a critical growth stage may have greater value than an equal quantity supplied after damage has occurred.

Institutions and evidence

ICAR-CRIDA's January 2025 Hyderabad training for farmers from Mancherial covered rainwater management, cropping systems, post-harvest value addition, livestock and pest management; this supports a **whole-farm risk-management approach**, not a quantified Telangana-wide yield claim. Telangana's Directorate of Economics and Statistics separately tracks rainfall and crop area, production and yield. To test a district assertion, align rainfall observations with the crop season and the same administrative geography, and distinguish actual field observations from recommended practice. **Mains conclusion:** resilience is a combination of moisture management, seed and market access, not merely a higher annual rainfall figure. [Sources: ICAR-CRIDA 2025; Telangana DES agriculture statistics; TNAU dryland agronomy.]

2. Crop patterns and place-specific trade-offs

Paddy, cotton, maize, red gram, millets and oilseeds illustrate differing water, soil, labour and market requirements. Paddy can benefit from assured canal or lift-irrigation supplies but may be ill-suited to chronically water-stressed groundwater zones. Cotton provides cash income but exposes producers to pest pressures, price volatility and market credit cycles. Pulses contribute to dietary protein and rotations while often having a different water-demand profile. A strong answer connects crop geography to **farm-gate pricing, procurement, groundwater availability, soil depth and processing chains**. Comparing cropping area across districts requires checking the relevant agricultural season and administrative boundary. Diversification is not viable without procurement, storage, local processing and demand.

Agronomic suitability versus financial viability

A crop can be physically feasible and still be an unsound choice for a small farmer. Paddy requires dependable water at critical stages and suitable soils; cotton combines commercial opportunities with pest-management, input-credit and price exposure; pulses and millets can offer rotation benefits but need viable seed, storage and buyers. These are conditional relationships, not a claim that one crop is always superior. Crop selection should be evaluated through expected net returns, downside losses, labour demand and irrigation reliability. A farmer's **net return** is sale value minus paid and imputed costs under a clearly stated accounting convention; gross output alone is not farm profitability.

An illustrative choice matrix

Suppose two villages have the same rainfall total. Village A has deep soil, functioning tank outlets and nearby procurement; Village B has shallow soil, uncertain borewell supply and distant markets. The same recommended crop package may perform differently. In A, a longer-duration crop could be considered after checking seasonal water availability. In B, shorter-duration crops, intercropping or staggered planting might limit the loss from a mid-season dry spell. Neither scenario establishes actual district yields. For a policy answer, compare **water demand**, **risk at flowering**, **market access**, **input credit**, and **post-harvest losses** before recommending diversification.

How to substantiate a crop-geography claim

The Telangana Directorate of Economics and Statistics identifies rainfall, land-use, area, production and yield statistics as distinct data series. Therefore a statement such as “cotton expanded” needs a named crop, kharif/rabi year, measured area and district boundaries; a rise in output might instead reflect higher yield. For irrigation dependence, compare the same season's irrigated area and water-delivery records rather than assume every paddy field uses canal water. ICAR-CRIDA's 2025 rainfed training included cropping systems, post-harvest management and value addition, supporting the integrated analytical frame but not any unreported state-level result. **Exam trap:** an increase in acreage is not proof of higher farmer income, and crop diversification without buyers can transfer rather than reduce risk. [Sources: Telangana DES; ICAR-CRIDA 2025; TNAU crop-planning guidance.]

3. Drought: diagnostic categories and targeted relief

A meteorological drought is a deficit relative to rainfall norms; an agricultural drought is insufficient root-zone moisture; a hydrological drought denotes depleted rivers, lakes or groundwater; socio-economic drought arises when water scarcity disrupts livelihoods and markets. Telangana can experience pockets of crop failure despite a comparatively satisfactory statewide rainfall figure. District contingency plans should therefore employ **rainfall departure, dry-spell frequency, soil-moisture anomalies, groundwater readings and reservoir storage** rather than one trigger. Relief must avoid exclusive dependence on land titles, which can exclude tenant cultivators and agricultural labourers. Long-term adaptation includes resilient seed, watershed work, farm ponds where hydrologically sound, supplementary irrigation and income diversification.

Four drought types do not share one measurement

A meteorological deficit is identified from precipitation relative to a reference period. Agricultural drought concerns water available to crops; hydrological drought concerns rivers, reservoirs and groundwater; socio-economic drought is the disruption of water-dependent activity and welfare. These processes can be sequential but need not begin or end together. A wet week can improve rainfall indices before groundwater or reservoir storage recovers. Conversely, an irrigation failure may harm a crop even without an unusually low district rainfall total. Do not classify drought from a single annual state average.

A reproducible mandal-level diagnosis

First record rainfall by week and its departure from an appropriate long-term normal; note the baseline and spatial scale. Next inspect sowing dates, dry spells around germination and flowering, crop-condition observations and root-zone moisture where available. Then check tank storage, groundwater monitoring and whether irrigation actually reached the command area. Finally examine labour demand, fodder availability and household coping responses. These indicators answer different questions; they should not be combined into an unexplained “drought score.” A remote-sensing vegetation anomaly can flag stress but may also reflect crop choice, sowing date or land-cover changes.

Worked interpretation and policy response

In a **hypothetical** mandal, suppose cumulative seasonal rainfall is near normal but a three-week gap occurs immediately after sowing. A meteorological seasonal summary alone may miss the crop loss. Short-term action could include extension advice on resowing where agronomically appropriate, seed access, drinking-water and fodder planning, and transparent eligibility for tenants and labourers. Long-term action includes soil-water conservation, aquifer management and diversified income. India's National Remote Sensing Centre authors, writing in IMD's *MAUSAM* (2016), discuss spatial extent, severity and persistence in agricultural-drought monitoring. Their methodological review is not a Telangana drought declaration. CGWB's 2024 Telangana groundwater assessment separately estimates recharge and extraction; groundwater status must be evaluated at the appropriate assessment unit rather than inferred from one state's average. **Exam conclusion:** diagnose the affected livelihood mechanism before selecting relief. [Sources: IMD MAUSAM 2016; CGWB Telangana 2024 assessment.]

4. Irrigation taxonomy: canal, tank, well and lift system

Canal irrigation draws from diverted or stored surface water, creating head–tail distribution issues, seepage and maintenance costs. **Tank irrigation** captures local runoff and can support village-scale ecosystems and recharge, but tanks require functioning feeder channels and safe embankments. **Wells and borewells** provide flexible private access yet can intensify collective depletion when pumping decisions are uncoordinated. **Lift irrigation** can serve elevations above gravity canal command, but capital costs, pumping energy and operational expenditure must be assessed. Merely counting irrigated hectares risks double-counting repeat seasonal crops; distinguish **net irrigated area, gross irrigated area and irrigation intensity**. Distributional equity demands monitoring delivery to tail-end and marginal holdings.

Worked comparison: command-area reliability, not merely construction

Consider two irrigation projects with the same sanctioned command area. A gravity canal may deliver adequate water near its head while the last distributary receives water too late for a critical crop stage. A lift scheme may reach a higher plateau, yet its service depends on electricity availability, pump maintenance and operating finance. A restored village tank may supply fewer hectares on paper but provide timely protective watering to many small plots. Therefore the relevant comparison is not simply hectares 'created'; it is **actual seasonal delivery, timing, reliability, cost per unit of delivered water and who receives it**. For exam answers, distinguish the design command, the potentially irrigable area and the area that actually received irrigation during the season.

Accounting trap: net irrigated area counts a physical parcel once even if it is irrigated in multiple crop seasons. Gross irrigated area counts irrigated cropped area across those seasons. Their ratio, expressed as a percentage, is irrigation intensity. A rise in gross area may result from repeated cropping on existing land rather than expansion to previously unserved farmers. This distinction matters when evaluating irrigation schemes in Telangana.

Catchment-to-field chain: a tank receives runoff through a feeder network; storage depends on rainfall, siltation and upstream withdrawals; safe release depends on sluices and channels; farm benefit depends on the command layout and crop calendar. Desilting without restoring feeders or distributaries can fail to increase useful delivery. Similarly, a canal built without drainage provision can create waterlogging or local salinity. The governance question is whether maintenance budgets, water-user participation and transparent tail-end allocations continue after construction.

Evidence to request: reservoir or tank water levels at defined dates, inflow/outflow records, actual command deliveries, farm-size distribution, pumping electricity, and annual maintenance spending. A single inauguration photograph, construction cost or project target is not a defensible outcome indicator. These are analytical evaluation criteria, not claims that a particular Telangana scheme has achieved them.

5. Mission Kakatiya: tank system revival

Mission Kakatiya was framed as a programme to restore minor irrigation tanks and associated systems. The exam-worthy mechanism is not 'desiltation' alone: capacity recovery is achieved only if feeder channels, sluices, bund safety, surplus-weir functioning and irrigation distribution are addressed together. A tank may also recharge wells, support fisheries and buffer local flood peaks. However, benefits should not be assumed from the tonnage of removed silt; verification requires **pre- and post-intervention storage surveys, seasonal water spread, groundwater monitoring, command delivery and farmer access**. Silt reuse on fields depends on physical and chemical quality and transport economics. Good governance includes tank-user participation and prevention of renewed catchment encroachment.

Source-critical case study: Mission Kakatiya's historical baseline

The Government of Telangana's Mission Kakatiya description records an enumeration undertaken in **July 2014**, covering departmental minor-irrigation tanks, panchayat-raj tanks, percolation tanks, forest tanks, private kuntas, anicuts and check dams. It reported approximately **46,531 minor-irrigation sources** as the programme's historical planning baseline. That number must not be reproduced as a newly surveyed **2026** count or treated as proof that all those sources were successfully restored. The original programme proposed phased restoration and linked the objective to small and marginal farmers' agriculture-based income. Its listed works include desilting, restoring feeder and irrigation channels, repairing bunds, sluices and weirs, and possible full-tank-level adjustments where feasible. [K1–K3]

Causal pathway and possible failure: removing sediment may recover part of a tank's effective storage, but only if inflow reaches it; bund and weir repair may improve safe retention, but poorly designed work can create downstream risk. Reliable water in the command may allow a protective irrigation at flowering; whether that translates into income depends on landholding, crop prices and access to water. Reusing silt on fields may alter soil texture or nutrient supply, but the benefits depend on testing, haulage cost and field conditions. Recharge effects cannot be assumed uniform: underlying geology, residence time and extraction patterns matter.

Evaluation design: compare the same tank before and after restoration across more than one monsoon; record rainfall, water spread, sediment storage, groundwater observation wells, actual command deliveries and distribution among head/tail users. A nearby unrestored but otherwise comparable tank can provide context, though selection bias and rainfall differences remain. Track negative effects too, such as erosion, encroachment, downstream-flow reduction or inequitable allocation. An increase in desilted volume is an **output**; dependable irrigation and livelihood changes are **outcomes**. The government portal is evidence of stated design and the 2014 enumeration, **not an independent impact evaluation**. Source: https://www.telangana.gov.in/mission-kakatiya/ .

6. Groundwater and the common-pool problem

Telangana's predominantly hard-rock aquifers make groundwater a common-pool resource with spatially variable fractures. One farmer's pumping can affect neighbouring wells even if pumps stand on separate plots. Electricity pricing, subsidised borewell drilling, assured crop purchasing and fragmented water rights can interact to encourage excessive extraction. Measures such as recharge pits are useful only where permeability and contamination risks permit. The **aquifer approach** maps hydrogeological units rather than stopping at village boundaries; it combines water-level time series, pumping estimates, recharge conditions, crop demand and negotiated community limits. Strong policy combines reliable energy, metering or proxy accounting, incentives for lower-water crops, conjunctive surface/groundwater use and explicit protections for smallholders.

Why an aquifer budget cannot stop at a village boundary

The Central Ground Water Board's **2024 aquifer-management plan for Maheshwaram, Shamshabad and Kothur blocks in Ranga Reddy district** provides a directly relevant example of groundwater assessment at a hydrogeological scale. The publication identifies geological, geophysical, hydrological and hydrochemical analysis as inputs to aquifer mapping. It should not be confused with a statewide groundwater estimate or proof that every Telangana aquifer behaves alike. [K5]

Mechanism: in a fractured hard-rock setting, wells may draw from weathered material and connected fractures with very uneven storage and transmissivity. Two wells at similar depth can therefore have different yields. Recharge from a tank or check dam depends on the local subsurface and may not immediately replenish the most heavily pumped fracture system. Rainfall infiltration is only one side of the balance; irrigation pumping, domestic supply and industrial abstraction are other withdrawals. A falling post-monsoon water level may reflect long-term extraction, a poor recharge season, changed measurement conditions or a combination; diagnosis needs a time series.

Illustrative water budget: let annual usable recharge be R, total extraction be E and a prudent reserve for ecological and drinking-water needs be B. A planning screen asks whether E is persistently greater than R minus B, but actual official assessments use defined methodologies and uncertainty bounds. This algebra is a teaching aid, not a measured Telangana aquifer calculation. Groundwater cannot be sustainably managed by multiplying the number of recharge pits alone. Test recharge suitability, water quality and possible contamination; then pair demand management with monitoring.

Governance and equity: a farmer with capital may deepen a borewell while a neighbour's shallow well fails. Community budgets, water-level disclosure, cropping advice and access to surface-water alternatives can reduce the inequity, but restrictions must protect drinking water and vulnerable farmers. An exam answer should distinguish a **CGWB mapped hydrogeological unit** from administrative district averages, and distinguish **observed water levels** from modelled sustainable yield. Source: https://cgwb.gov.in/cgwbpnm/public/publication-detail/1634 .

7. Cement and sugar: material- and resource-oriented industries

Cement plants are influenced by proximity to **limestone**, fuel, roads, demand centers and environmental regulation. Quarrying raises dust, landscape and groundwater concerns, while the kiln process emits carbon dioxide from both fuel and calcination. Sugar factories depend on the perishability and bulkiness of harvested cane, irrigation and haul distance; cane is a water- and land-intensive crop whose regional suitability varies sharply. The analytical comparison is **location factor → input chain → employment → ecological footprint**. In mains answers, note that a factory's existence does not demonstrate inclusive local growth: seasonal labour, farmer payment delays, pollution and competing water uses need evaluation.

Why the two industries choose different sites

Cement is an example of a **mineral- and energy-linked manufacturing chain**. Limestone must be extracted, crushed and processed into clinker at high temperature; grinding and distribution then connect the plant to construction markets. A limestone deposit is a necessary geological advantage, but not a sufficient investment case: extraction permissions, power and fuel cost, road or rail loading, water, local settlements and demand also shape location. The Suryapet District Industries Centre identifies cement manufacturing in its local industrial profile, providing a Telangana example; it does not establish a complete statewide plant inventory or current capacity. For a district case study, distinguish a functioning plant from a proposed unit and verify the observation year.

Sugar as an agricultural processing location problem

A sugar mill's location is constrained by the spatial concentration of cane cultivation, harvest season and time-sensitive transport from farms. Farmers need reliable crushing schedules and transparent payment; mills need adequate cane throughput and access to energy, water and by-product markets. This makes cane production, irrigation and industrial policy interdependent. A hypothetical mill near a reliable road but far from cane suppliers can face higher procurement cost than one embedded in a producing belt. Conversely, a nearby mill is not automatically viable if farmers switch crops because of water scarcity or delayed payment. The Telangana Industries and Commerce Department explicitly includes sugar industries within its remit, but this institutional description is **not** evidence of present operating capacity or mill profitability.

Environmental and distributional assessment

For cement, distinguish quarry impacts, kiln fuel emissions and process carbon dioxide from limestone calcination. For sugar, distinguish field-level irrigation demand, cane transport, factory wastewater and the use of by-products. Compare actual emissions and discharge monitoring rather than treating all plants as equally polluting. A mains answer should ask who gains employment, who bears water and land costs, whether suppliers are paid on time, and whether local transport infrastructure is maintained. **Evidence checklist:** plant operational status, mineral or cane sourcing radius, verified capacity utilisation, employment quality, water use, compliance records and the date of each observation. [Bounded sources: Suryapet DIC; Telangana Industries and Commerce Department.]

8. Pharmaceuticals: Hyderabad's research and manufacturing ecosystem

Hyderabad's pharmaceutical and life-sciences ecosystem links research institutions, bulk drug/active pharmaceutical ingredient manufacturing, formulation units, quality control and global supply chains. Concentration supports skilled labour pools, specialised suppliers and regulatory expertise; this is an **agglomeration economy**. It also presents challenges: effluent management, land use conflict, environmental compliance and the need for high-skilled but inclusive employment. Do not equate an announced industrial park with completed capacity or operational employment. A competitive answer describes both upstream API chemistry and downstream formulations, clinical research, logistics, compliance and innovation, rather than merely listing 'pharma' as a growth sector.

The value chain is wider than medicine factories

An active pharmaceutical ingredient (API) is a biologically active component used in a medicine; a formulation combines ingredient, excipients and dosage technology to make a usable product. Research and development, analytical testing, clinical studies, quality assurance, regulatory submissions, cold-chain logistics and packaging form distinct parts of the life-sciences economy. A city may host many such functions without each being physically located in the same industrial estate. Telangana's official Invest Telangana life-sciences overview describes Genome Valley, Medical Devices Park and Green Pharma City as major clusters or initiatives. It is a government investment-promotion description; its company totals and projected employment must not be treated as independently audited outcomes.

Why Hyderabad attracts clustered investment

The relevant mechanism is not simply 'good infrastructure'. A skilled workforce, specialised laboratories, supplier networks, research institutes, transport links and repeated business relationships can lower search and coordination costs. A manufacturer may choose proximity to testing and packaging vendors even when industrial land elsewhere is cheaper. This is **agglomeration**, but concentration can also raise rents and infrastructure pressure. Differentiate existing Genome Valley activity from proposed or developing facilities. The Telangana Next-Gen Life Sciences Policy 2026–2030 presents Green Pharma City with planned waste-management and environmental infrastructure; that policy statement is an intention or design claim, not proof that every facility is commissioned and compliant.

Public-interest tests and a district strategy

Pharmaceutical production can create high-skilled jobs, technical services and export opportunities, but chemical handling, solvent recovery, effluent treatment and hazardous waste require verifiable oversight. Regulatory approval for a medicine is different from environmental clearance for a factory; neither should be inferred from a press release. District-level development policy should identify realistic feeder industries—precision equipment, packaging, logistics or skill centres—rather than assume an entire research cluster can be relocated. **Worked comparison:** if two sites offer similar land costs, evaluate skilled-labour access, reliable utilities, supplier lead times, transport, treatment capacity and compliance records. An exam conclusion should separate **announced investment, completed infrastructure, operating output and quality employment**. [Bounded sources: Invest Telangana life-sciences overview; Telangana Next-Gen Life Sciences Policy 2026–2030.]

9. Electronics, IT, ITIR and SEZs: separate policy instruments

Telangana hosts IT service clusters, electronics manufacturing initiatives and special economic zones, but these terms denote different activities and instruments. An **SEZ** is a notified zone with a specific regulatory and fiscal framework; an **industrial corridor** is a wider connected investment geography; **ITIR** is a policy/planning designation whose proposed status must be checked rather than assumed implemented. IT services rely on skilled labour, connectivity, client access and business ecosystems, while electronics manufacturing additionally needs components, logistics, power quality and high-volume supply chains. The value-added question is whether investment builds local supplier depth, high-quality jobs, women’s workforce participation and durable research capacity.

Legal test: a proposed SEZ is not a notified SEZ

The **Special Economic Zones Act, 2005**, provides a useful primary-source distinction for industrial geography. Section 3 describes proposals to establish an SEZ; section 4 governs establishment and authorisation; section 2(za) defines an SEZ by reference to notification under the Act. Therefore, a press announcement, industrial-park proposal, memorandum of understanding or corridor plan is **not itself evidence of a legally notified SEZ**. [K6] For a named Telangana project, students should check the government notification, approved area, current operational status and actual units rather than infer completion from the proposal date.

Four policy categories: an IT services cluster describes a geographic concentration of firms and workers; an electronics manufacturing cluster concerns factories and supply chains; an ITIR was a policy/planning instrument; an SEZ has a particular statutory approval and notification route. These categories can overlap geographically but are not interchangeable. A planned project may change scope, be delayed, or remain unimplemented; its status should always be dated.

Economic chain: agglomeration lowers search and coordination costs when firms can recruit specialised workers and buy from nearby suppliers. However, high office occupancy does not prove widespread quality employment, and a manufacturing announcement does not establish domestic component value addition. Evaluate supplier linkages, realised exports, local procurement, formal employment, women's participation, skill

requirements and water/power use. Displaced landholders, informal workers and small suppliers may experience benefits and costs differently.

Fiscal caution: SEZ tax and customs incentives have changed over time. Do not repeat an old incentive list as if every exemption remains available in 2026. The Department of Commerce itself notes sunset clauses and withdrawn exemptions in its guidance. Quote the provision and applicable date for any claim about tax treatment. Sources: https://www.indiacode.nic.in/indiacode/handle/123456789/2042?view_type=browse and https://www.sezindia.nic.in/index.php/facilities-and-incentives .

10. Tourism geography: circuits, livelihoods and carrying capacity

Hyderabad's heritage tourism is supported by monuments and museums, while districts host temple, eco-, cultural and nature attractions such as **Ramappa**, **Warangal**, **Bhadrachalam** and forest-oriented circuits. Tourism's contribution is not solely arrivals: local spending, transport, crafts, accommodation, food supply and jobs matter. Excess visitor intensity can damage fragile monuments and increase waste, water stress and habitat disturbance. At World Heritage properties, buffer-zone decisions and Heritage Impact Assessments constrain large works. In 2026 the UNESCO World Heritage Committee addressed Ramappa's wider irrigation setting, including Lake Ramappa, and stressed review of proposed projects before implementation. This makes **heritage landscape conservation** a distinctive, recent mains point rather than a generic call for more tourists.

From an attraction list to a geographic tourism circuit

A tourism circuit connects multiple destinations through feasible travel time, transport, interpretation, food, accommodation and locally provided services. Hyderabad can serve as a gateway, but a Warangal–Palampet heritage itinerary requires different visitor management from an eco-tourism route near a protected habitat. A high number of visitors at a monument does not itself establish that surrounding households receive a fair share of spending. Measure overnight stays, local procurement, guide income, seasonality, accessibility and the share of visitor expenditure retained locally. Avoid attributing every increase in hotel activity to one heritage site without a comparable baseline.

Ramappa: the monument and its working landscape

UNESCO's World Heritage entry describes Ramappa Temple as part of a wider setting of agricultural land, forest and the Kakatiya-built reservoir and irrigation system. This matters because the temple's heritage value is not confined to the walled structure. UNESCO Decision 47 COM 8B.38 (2025) approved a minor property-boundary modification but **referred back** the proposed buffer-zone extension to cover canals and Lake Ramappa; the two decisions must not be conflated. The 2026 state-of-conservation decision continued to address proposed work and heritage impact assessment. It did not certify that all planned development or lake works were completed. A proposed visitor facility must be assessed for visual impact, traffic, waste, water demand and effects on the cultural landscape.

Tourism with a conservation budget

Carrying capacity is not a fixed statewide visitor number. A site may face different limits from path erosion, crowding, drinking-water availability, wildlife disturbance or ritual use. A management plan can schedule visits, protect sensitive zones, provide accessible routes and ensure waste collection, while preserving resident livelihoods. A useful mains evaluation matrix has four columns: heritage condition, visitor experience, local earnings and ecological pressure. **Policy test:** increased arrivals are a success only if conservation standards and local benefits are maintained. [Bounded sources: UNESCO Ramappa property record; UNESCO Decisions 47 COM 8B.38 and 48 COM 7B.11.]

11. Handicrafts and household production systems

Pochampally ikat weaving, **Gadwal sarees**, **Narayanpet textiles** and other regional crafts illustrate geographically anchored skill systems. A product label alone is insufficient: weaving households contend with yarn price swings, design changes, powerloom competition, market intermediaries and income insecurity. The policy response combines verified geographical indication/branding where applicable, design training, online market access, affordable working capital and bargaining power through producer collectives. Beware of treating every named craft as produced exclusively in a modern district boundary; skill and supply chains cross borders. For mains, contrast artisanal cultural value with measurable labour income and generational skill continuity.

Production geography and the artisan value chain

Pochampally ikat is not simply a printed pattern. The Ministry of Textiles handicrafts description explains a resist-dyeing process applied to yarn before weaving; aligning dyed warp and/or weft threads demands specialised skill. This production method helps distinguish ikat from surface printing in an objective question. Telangana Tourism also identifies Gadwal weaving, Nirmal paintings, Cheriyal scrolls, Pembarthi metalwork and Adilabad Dokra as distinct craft traditions. Their raw materials, workshop organisation, markets and historical locations differ, so a single 'handicraft industry' policy cannot be assumed to fit them all. The Hyderabad district portal describes Dokra's lost-wax metal-casting process, which is technically different from ikat weaving.

Why cultural recognition does not guarantee household income

A geographical indication can protect the association between a product and its origin under the applicable registration, but it does not by itself guarantee high wages, authentic raw materials or steady orders. The economic chain runs from design and yarn or metal procurement through skilled production, quality control, aggregation, wholesale or online sale and payment. Artisan income can be squeezed by input inflation, delayed payment, imitation products and dependence on intermediaries. A cooperative may improve purchasing and bargaining power, yet it still needs transparent accounts, design support and demand. Compare the selling price of a finished saree with the artisan's net earnings after materials, household labour and time, rather than using retail price as a proxy for welfare.

A measurable preservation-and-livelihood plan

For a Pochampally cluster, track verified working looms, artisan hours, net income, training outcomes, orders fulfilled and young entrants learning the technique. For Cheriyal painting, examine whether storytelling knowledge and commissions survive, not merely whether souvenirs are sold. Digital catalogues can broaden reach, but reliable fulfilment and protection from misrepresentation matter. **Mains conclusion:** preserve the production skill, not only the label, while strengthening income security and intergenerational transmission. [Bounded sources: Government of India Handicrafts Pochampally Ikat description; Telangana Tourism Arts and Crafts; Hyderabad district handicrafts page.]

12. Roads, railways and uneven economic integration

Road connectivity links villages to procurement centres, medical services, schools and industrial markets. Railways can lower per-unit logistics cost for selected freight and passenger corridors, while road transport offers last-mile flexibility. Spatial benefits differ: a highway passing near a village does not automatically give farmers a safe interchange or reliable market access. Examine **travel-time reliability, freight cost, multimodal transfer, road safety and maintenance**, not only kilometres built. Hyderabad's concentration creates a hub-and-spoke structure, with the risk that district towns become labour-supply catchments rather than independent job centres. Industrial decentralisation requires serviced land, reliable logistics and locally relevant skill institutions.

Connectivity is a network service, not a road-length statistic

The National Rural Infrastructure Development Agency defines the PMGSY core network around basic all-weather access from a habitation to a connected road or market centre. Its FAQ clarifies that a habitation, rather than an entire revenue village, is the programme's unit of connectivity; an all-weather road need not be a black-topped surface if drainage and year-round passage are assured. These definitions matter in Telangana's dispersed rural settlements: counting kilometres without checking whether people can actually reach markets or clinics is an incomplete indicator. A road can be built but become seasonally impassable if culverts or maintenance fail. Compare door-to-door travel time before and after works, with seasonal variation, rather than assuming a nominal map connection is usable.

Rail freight and road access perform different functions

Bulk commodities may gain from rail's scale on suitable corridors, whereas collection from farms, industrial estates and households normally requires road access. A factory's logistics chain may involve a truck to a rail siding, rail to a distant terminal, then another truck to a customer. The South Central Railway's official profile records a major organisational change effective 1 June 2026, with the Vijayawada, Guntakal and Guntur divisions transferred to South Coast Railway. Thus historical railway totals for the former South Central Railway cannot be compared uncritically with the reorganised 2026 system. An examination answer must specify the railway zone, reference date and indicator before quoting passenger or freight totals.

Who receives the benefit?

Suppose a district gets a new highway but no safe village access, bus frequency or cold-storage connection. Through-traffic may improve while farmers' effective market access remains unchanged. Conversely, a maintained all-weather link can reduce missed school or medical trips without any major industrial investment. The appraisal should distinguish construction expenditure, traffic speed, accident risk, maintenance funding, last-mile services and distributional effects on remote or tribal settlements. **Mains test:** evaluate access for people and goods rather than celebrating project announcements. [Bounded sources: NRIDA PMGSY Core Network and FAQ; South Central Railway official profile, 2026.]

13. Population: stock, rate, structure and boundary traps

Census 2011 remains a common baseline for official long-run district comparisons, but Telangana's subsequent district reorganisation changes the units of observation. **Population density = population/land area**; growth rate needs a period and consistent geography; sex ratio and child sex ratio are distinct indicators; literacy rates depend on the specified age base. An ageing profile can coexist with youthful migration to Hyderabad. Avoid comparing a new district's 2026 population estimate with an undivided 2011 district value without a spatial crosswalk. A high-quality answer states the source, year, administrative unit and limitation for each statistic. The demographic dividend is realised through education, health, employment and women's participation, not automatically through a large working-age cohort.

Read the Census denominator before comparing districts

The Telangana government state profile reports Census 2011 population of about 350.04 lakh, density of 312 persons per square kilometre, overall sex ratio of 988 females per 1,000 males and literacy rate of 66.54%. These are **2011 Census-based figures**, not measurements made in 2026. The Directorate of Economics and Statistics provides the more precise 2011 count of 35,003,674 people. An apparent discrepancy between 350.04 lakh and 35,003,674 is rounding, not a different census. The state profile also distinguishes rural and urban population and reports a child sex ratio of 932, which must not be substituted for the all-age sex ratio. Literacy is calculated for persons aged seven and above under the Census definition, not as literates divided by total population including infants.

Boundaries, growth and rates

For an inter-district comparison, first choose a common district map and time period. Telangana's post-2011 district reorganisation makes direct ranking of an erstwhile large district against a new smaller district potentially misleading. Population density is a stock divided by area; decadal growth compares populations at two dates using consistent boundaries. **Illustrative calculation:** a hypothetical district with 2.0 million people over 5,000 square kilometres has density 400 per square kilometre; if the same territory had 1.8 million ten years earlier, growth is about 11.1%. This arithmetic does not describe any actual Telangana district. Sex ratio, child sex ratio, literacy, worker participation and urban share have different denominators and should be reported separately.

The demographic dividend is conditional

A high working-age share can offer a labour-supply opportunity but does not prove productive employment. Assess schooling, skills, health, mobility, women's participation and access to non-farm jobs. Hyderabad-bound migration can alter the age structure of both sending and receiving areas, so aggregate state indicators can conceal district inequalities. **Evidence rule:** give source, year, geography and denominator next to every number; use a spatial crosswalk before attributing change to district performance. [Bounded sources: Telangana State Profile; Telangana Directorate of Economics and Statistics, Telangana at a Glance.]

14. Tribal geography and historical exclusion

Scheduled Tribe populations are not uniformly distributed. Forested and hill areas, particularly in northern and eastern Telangana, have distinct settlement, language, resource-access and infrastructure patterns. Specific communities and regions have varied histories; **Adivasi land rights, forest produce, displacement and access to schools and healthcare** cannot be reduced to a generic poverty description. Road construction may improve health access but also facilitate extractive pressure and land speculation. Projects require informed participation and culturally appropriate service delivery. Tribal-area governance must be discussed in relation to Fifth Schedule protections and, where applicable, the Panchayats (Extension to Scheduled Areas) Act, 1996, and the Forest Rights Act, 2006, with attention to implementation rather than simply naming laws.

Territory, tenure and administrative categories

“Tribal area” is not a synonym for all rural forest land. Scheduled Tribe status concerns notified communities, while Scheduled Areas have a separate constitutional geography. A district may include both Scheduled and non-Scheduled areas. Development analysis must identify the particular settlement, customary resource use, legal tenure and administrative jurisdiction before applying a generic policy prescription. Land alienation, displacement and restricted access to minor forest produce can affect livelihoods differently from the absence of a road or school. A new road may improve emergency care but also change forest access, markets and extraction pressures; both effects deserve assessment.

Distinguish the rights framework

The Ministry of Tribal Affairs describes the Forest Rights Act, 2006 as recognising specified **individual** rights (including eligible self-cultivation and habitation) and **community** rights (including certain forest-resource and customary uses). It also recognises community forest-resource management and responsibilities relating to conservation. These rights are not interchangeable with a general entitlement to ownership of every forest parcel. Under the FRA Rules, the Gram Sabha initiates claims and forwards resolutions through the prescribed committee process; submission of a claim is not the same as a final recognised title. PESA, 1996 concerns governance in applicable Scheduled Areas and must not be presented as automatically operative throughout Telangana. Each scheme needs its own territorial and legal check.

An evaluation framework for Telangana

A district case study should report: the share of settlements with functional schools and health services, actual travel time in the monsoon, language-appropriate instruction, access to forest produce markets, pending versus recognised FRA claims, and outcomes for women and smaller habitations. Do not substitute a sanctioned budget or kilometres of new roads for demonstrated household benefit. Where a livelihood project changes land or forest use, distinguish consultation requirements, claim recognition, rehabilitation and implementation; these arise under different legal instruments. The ministry's official FRA overview supports these rights categories and responsibilities, but it does not verify Telangana district implementation outcomes. **Mains conclusion:** inclusion requires secure rights, accountable services and ecological sustainability, assessed together rather than as competing slogans. [Sources: Ministry of Tribal Affairs FRA overview and Act/Rules booklet.]

15. Policy synthesis: regional balance with measurable outcomes

Telangana's development challenge is simultaneously agrarian, industrial, spatial and social. An integrated strategy would connect dryland productivity with processing clusters, reduce irrigation inequality, strengthen district-town employment, support women's workforce participation and preserve the environment. For monitoring, select **tail-end irrigation delivery, groundwater trend, farm income variability, district-wise quality employment, craft household earnings, travel-time access and tribal land security**. Do not substitute expenditure or number of schemes for outcomes. A professional conclusion relates institutions to measurable well-being: agriculture, industry, transport and population form one connected economic geography, not unrelated subheadings.

Integrate four linked policy systems

An agricultural strategy that raises output without water budgeting can worsen groundwater stress. An industrial strategy that creates parks without transport and skills may fail to create durable district jobs. A tourism strategy that attracts visitors without conservation planning can damage the heritage resource on which it depends. A demographic strategy that counts young people without tracking employment may overstate the dividend. Telangana therefore needs coordinated district plans that connect crop and water data, functioning industrial supply chains, access to services and environmental safeguards. The appropriate planning unit differs by problem: aquifers cross mandal boundaries, commuters cross municipal borders, and craft production networks cross district lines. Coordination should follow the geography of the problem rather than administrative convenience alone.

Build an outcome dashboard with explicit baselines

A practical dashboard can include crop yield variability, groundwater level trend by monitored aquifer, tank tail-end delivery, travel time to the nearest reliable market, verified industrial jobs, women's labour-force participation, artisan net income, visitor-related waste and tribal land-claim outcomes. Each measure needs a unit, data owner, baseline year and reporting frequency. A higher scheme allocation is an **input**, a completed tank desilting job is an **output**, reliable irrigation during a dry spell is an **outcome**, and long-run household resilience is an **impact**. These levels should not be mixed. A useful exam table can pair each intervention with a plausible benefit, a distributional risk and a measurable indicator.

Worked district comparison and accountability

Imagine District A has high industrial investment announcements but poor job retention, while District B has modest new investment yet strong local procurement and lower travel times. It is not possible to call A more developed without checking real jobs, wages, access and environmental costs. The same logic applies to a tank programme: desilting volume alone does not prove equitable command-area water. Evaluate projects at baseline and follow-up using comparable definitions, and disclose missing data. **Conclusion:** regional balance means demonstrable gains for households across agriculture, industry and services, subject to ecological and legal safeguards—not a simple equal allocation of projects to every district. [Synthesis grounded in the institutional sources registered below; hypothetical comparison is not observed evidence.]

Additional case-study explanations — prior six-section repair (potential overlaps to deduplicate)

Original substantive partial repair — 25 October 2026. Existing published PDF unchanged. Independent academic audit pending.

1. Agro-climatic diversity and the error of a single Telangana average

Telangana agriculture cannot be reduced to one rainfall figure or one dominant crop. The Deccan plateau contains dryland tracts, black and red soils, tank-fed pockets, canal commands and peri-urban farming belts. Farmers' choices depend on rainfall timing, soil moisture, groundwater depth, irrigation reliability, credit and market access. A district with relatively high annual rainfall can still face severe crop stress when precipitation is concentrated in a few storms and dry spells coincide with flowering. Similarly, an irrigation command may report a large designed area but deliver water to fewer hectares in a drought year. The relevant analytical unit is often the watershed or mandal, not the entire state. For a mains answer, distinguish gross cropped area from net sown area, gross irrigated area from net irrigated area, and cropping intensity from irrigation intensity. These definitions prevent exaggerated claims that a new project automatically makes every hectare permanently irrigated. A robust agricultural strategy combines watershed work, soil testing, drought-resilient varieties, market information and access to extension services rather than assuming that one crop or one dam can serve all regions.

2. Groundwater, tanks and canals: complementary rather than rival systems

The historic tank network of Telangana stored monsoon runoff, supported livestock and enabled limited irrigation, while modern borewells increased farmers' control over water timing. But uncontrolled groundwater extraction can lower water tables, increase pumping costs and create unequal access between farmers who can finance deep wells and those who cannot. Canal projects can supply larger command areas but require dependable inflows, land acquisition, distributary maintenance and water-use planning. Tank restoration is therefore not a substitute for groundwater regulation or canal efficiency; these interventions operate at different scales. The policy question is how to integrate them. A village water budget should estimate rainfall, recharge, domestic demand, crop water requirements and the ecological needs of streams. Farmers can then adjust crop patterns and scheduling. In an answer, discuss both the benefits of improved irrigation and the risks of water-intensive crops, power subsidies and upstream-downstream conflict. Claims about project performance should cite actual water releases and irrigated hectares for a specified year, not promotional capacity alone.

3. Crop choice, price risk and agrarian distress

Cotton, paddy, maize, pulses and horticultural crops involve different combinations of water demand, labour, input cost, storage and price volatility. A farmer may select a high-return crop because of one good season, then face losses when rainfall fails, pests spread or prices fall. Indebtedness is shaped by institutional credit access, informal borrowing, tenancy, health expenses and the timing of procurement payments. A meaningful assessment of distress must distinguish crop failure from price collapse and both from household indebtedness. A policy response should include risk-appropriate insurance, reliable extension, pest surveillance, affordable credit and transparent market information. Tenant farmers and women cultivators may face barriers when land title is used as the main gateway to benefits. For Telangana, the correct analytical method is to combine household survey evidence, crop-cutting estimates, market price series and district irrigation data. Avoid asserting a universal causal explanation for farmer suicides; individual events require verified records and sensitive treatment.

4. Industrial geography: Hyderabad concentration and district opportunity

Hyderabad’s information technology, pharmaceuticals, biotechnology and service industries create a metropolitan concentration of skilled jobs and infrastructure. Other districts contain mining, agro-processing, textiles, cement, food processing and smaller manufacturing clusters, but their growth depends on connectivity, reliable power, skills and access to finance. State-level industrial output can rise while opportunities remain geographically uneven. A policy evaluation should therefore examine district employment, formal and informal enterprises, value added, wages and environmental effects rather than simply counting investment announcements. Industrial corridors can lower transport costs but may also intensify land conversion and pressure on water. Telangana’s development challenge is to connect rural producers to processing, logistics and urban markets while maintaining labour standards and environmental safeguards. An effective mains answer weighs agglomeration benefits against spatial inequality, proposes targeted infrastructure and technical training, and insists on independent assessment of realised jobs rather than projected memorandum-of-understanding figures.

5. Population, migration and urbanisation: the denominator problem

Population trends influence how development indicators are interpreted. A district’s school enrolment, hospital capacity or job count should be considered relative to age structure, migration and settlement patterns. Hyderabad’s growth reflects natural increase, intra-state migration and movement from other parts of India; treating every migrant as evidence of unfair access is methodologically wrong. Rural-to-urban movement can increase incomes but also produce housing shortages, informal settlements and pressure on transport and sanitation. A useful study distinguishes Census-defined urban areas from functional metropolitan regions and municipal boundaries, which may change over time. Population density alone does not measure service quality. For historical comparisons between Telangana and undivided Andhra Pradesh, researchers must reconstruct consistent territorial units, especially when districts were reorganised after 2014. Without that step, apparent growth rates can reflect boundary changes rather than real improvements. This is particularly important when preparing mains answers about regional disparities.

6. Integrated district planning and measurable accountability

Agriculture, irrigation, industry and population are linked through labour and resource flows. A new irrigation project may change crop choice, increase demand for seasonal workers, attract agro-processing and affect groundwater recharge. An industrial estate may generate employment but also compete with farmers for water. A district plan should therefore combine a water balance, agricultural risk profile, employment survey, skills map, transport plan and public-health assessment. Targets must distinguish outputs from outcomes: constructing a canal is an output, reliable delivery to tail-end farms is an outcome; announcing a factory is an output, sustained local jobs with safe conditions are outcomes. Citizen-facing dashboards should publish time series with definitions, baselines and independent audits. Such planning is a practical response to the regional-disparity debates central to Telangana history. It shifts attention from slogans to measurable improvements while recognising that distributional conflicts require democratic negotiation as well as technical analysis.

Quick revision — applied checkpoints

- Distinguish rainfed moisture source from dryland production constraint.
- Explain why rainfall timing can matter more than a state average.
- Contrast meteorological, agricultural and hydrological drought with separate indicators.
- Differentiate net/gross irrigated area and irrigation intensity.
- Judge Mission Kakatiya by command delivery and safety, not silt tonnes.
- Use aquifer boundaries, pumping and recharge together for water budgeting.
- Compare gravity canals and lift irrigation by energy and tail-end service.
- Link limestone and bulk transport to cement location; account for kiln emissions.
- Explain Hyderabad pharma clustering through suppliers, skills and regulation.
- Distinguish a legally notified SEZ from a proposed corridor or ITIR.
- Assess Ramappa heritage proposals using actual UNESCO decision status.
- Measure craft welfare through artisan earnings, not brand promotion alone.
- Harmonise district boundaries before demographic trend comparisons.
- Explain why tribal land rights need implementation and community participation.
- Judge regional balance through durable jobs, equitable irrigation and environmental outcomes.

25 original explained MCQs — NOT official PYQs

Original MCQ 1

What best distinguishes rainfed agriculture from dryland farming?

A. Rainfed describes the main moisture source; dryland describes moisture-limited production conditions
B. Rainfed always requires canals; dryland always uses borewells
C. Both are legally identical irrigation classifications
D. Dryland farming occurs only on black cotton soils

Key: A. Rainfed concerns reliance on precipitation; dryland focuses on production under limited and variable moisture. They overlap but are not synonymous.

Evidence class: bounded author-side teaching check (Cycle96): A is the intended conceptual distinction, supported at the level of rainfed/dryland crop-management approaches by ICAR-CRIDA (2025) and TNAU dryland guidance. B is contradicted by the meaning of rainfed; C invents legal identity; D incorrectly restricts soil type. Neither source provides a formal statutory definition, so independent textbook verification remains required.

Original MCQ 2

Why can an adequate state annual rainfall total coexist with crop failure in a mandal?

A. Every crop needs identical monthly rainfall
B. Long dry spells at germination or flowering can damage crops despite annual totals
C. Crop failure is unrelated to rainfall distribution
D. Rainfall totals determine farm prices directly

Key: B. Crop-stage timing and dry-spell duration matter alongside the annual total; local variation can be masked by statewide averages.

Evidence class: bounded author-side teaching check (Cycle96): B follows crop-stage moisture-risk reasoning in ICAR-CRIDA's rainfed training and the IMD-hosted agricultural-drought monitoring review. A wrongly assumes uniform crop timing, C denies a relevant mechanism, and D confuses rainfall with price formation. This is not a Telangana-specific observed crop-loss finding.

Original MCQ 3

Which evidence combination most directly diagnoses agricultural drought?

A. District highway kilometres and factory output
B. Monument visitor counts and tank names
C. Root-zone soil moisture, crop condition and dry-spell duration
D. Only the state's annual mean rainfall

Key: C. Agricultural drought concerns crop-available moisture, unlike a purely meteorological rainfall deficit.

Evidence class: bounded author-side teaching check (Cycle96): C addresses crop-available moisture and crop stress, consistent with the IMD-hosted 2016 NRSC agricultural-drought monitoring review. A and B measure unrelated activities; D ignores root-zone and timing evidence. The item has not undergone independent expert validation.

Original MCQ 4

Why is gross irrigated area often larger than net irrigated area?

A. It excludes wells
B. It counts only tanks
C. It excludes rabi cultivation
D. The same land irrigated in multiple seasons is counted more than once

Key: D. Gross irrigated area counts repeated irrigation across crop seasons; net irrigated area counts the physical land area once.

Evidence class: conceptual draft; primary-source key/distractor review pending (C04).

Original MCQ 5

Which is the strongest outcome measure for tank restoration?

A. Reliable seasonal water delivery to actual command farmers
B. Total sediment truckloads alone
C. Number of inauguration ceremonies
D. Estimated excavation spending

Key: A. Service reliability and distribution to farmers are outcomes; excavation is an activity or output.

Evidence class: partially official-source-correlated; item-level distractor audit pending (K1-K3).

Original MCQ 6

Which action best addresses groundwater depletion in hard-rock aquifers?

A. Assume every borewell has an independent underground reservoir
B. Combine aquifer mapping, pumping estimates, crop demand and community water budgets
C. Install recharge pits without checking geology or water quality
D. Measure only the deepest well once per decade

Key: B. Fractured hard-rock aquifers are spatially connected and variable; pumping and recharge require hydrogeological assessment.

Evidence class: conceptual draft; primary-source key/distractor review pending (C06).

Original MCQ 7

Which comparison correctly characterises gravity canal and lift irrigation?

A. Both require identical pumping energy
B. Gravity canals never need maintenance
C. Lift irrigation may serve higher elevations but needs pumping energy
D. Lift irrigation always costs less than gravity supply

Key: C. Lift systems can raise water to higher command areas, creating energy and operating-cost obligations.

Evidence class: conceptual draft; primary-source key/distractor review pending (C07).

Original MCQ 8

Why are cement plants frequently associated with limestone-bearing areas?

A. Cement is primarily assembled from imported finished bricks
B. Limestone is unrelated to cement raw material
C. Only urban tourism determines cement siting
D. Limestone is a major raw input and heavy bulk transport affects costs

Key: D. Cement location reflects limestone and other raw inputs, fuel, logistics, markets and environmental requirements.

Evidence class: conceptual draft; primary-source key/distractor review pending (C08).

Original MCQ 9

Which is a plausible industrial agglomeration mechanism in Hyderabad pharmaceuticals?

A. Specialised suppliers, skilled workers and regulatory services reinforce clustering
B. Every pharmaceutical facility produces only finished tablets
C. Cluster growth eliminates pollution risk
D. The presence of an industrial park proves operational employment

Key: A. Agglomeration can lower coordination costs through suppliers, skilled labour and shared services, without eliminating environmental risks.

Evidence class: conceptual draft; primary-source key/distractor review pending (C09).

Original MCQ 10

What distinguishes an SEZ from an industrial corridor?

A. An SEZ is simply a railway junction
B. An SEZ is a specifically notified regulatory zone; a corridor is broader connected geography
C. All corridors are automatically SEZs
D. An SEZ requires no legal notification

Key: B. SEZ is a statutory/regulatory designation, whereas corridor denotes wider spatial infrastructure and investment linkages.

Evidence class: conceptual draft; primary-source key/distractor review pending (C10).

Original MCQ 11

What is the correct interpretation of the historic Mission Kakatiya figure 46,531?

A. Number of tanks independently confirmed functional in October 2026
B. Number of completed modern lift schemes
C. A 2014 enumeration baseline of minor irrigation sources cited in programme planning
D. Number of UNESCO heritage irrigation structures

Key: C. The government portal uses 46,531 as an earlier enumeration baseline, not a current audited outcome.

Evidence class: partially official-source-correlated; item-level distractor audit pending (K2).

Original MCQ 12

What would show a handloom programme improved livelihoods rather than merely visibility?

A. A larger number of promotional banners
B. More named craft categories without sales evidence
C. More tourism posters alone
D. Sustained real artisan earnings, timely payments and stronger market access

Key: D. Livelihood effects require measures of earnings, payment terms and access to markets, not only branding.

Evidence class: conceptual draft; primary-source key/distractor review pending (C12).

Original MCQ 13

Why are 2011 census figures difficult to compare directly with newer Telangana district estimates?

A. Administrative district boundaries have changed and need geographic harmonisation
B. Density is never calculated from area
C. Literacy cannot be defined by age
D. Population counts are unaffected by boundary changes

Key: A. Changes to district boundaries alter the geographic denominator and population allocation; comparable series need crosswalks.

Evidence class: conceptual draft; primary-source key/distractor review pending (C13).

Original MCQ 14

Which definition correctly distinguishes population density from population growth?

A. Both mean persons per square kilometre
B. Density is persons per unit area; growth measures population change over a specified period
C. Density is births divided by deaths
D. Growth is total population divided by area

Key: B. Density is a stock relative to area, whereas growth compares population across dates using consistent geography.

Evidence class: conceptual draft; primary-source key/distractor review pending (C14).

Original MCQ 15

Which statement best describes the demographic dividend?

A. A large youth population guarantees jobs
B. A higher population density guarantees wages
C. Potential gains require education, health, participation and productive employment
D. It is identical to the total fertility rate

Key: C. Age structure creates potential, not automatic growth; human capital and employment institutions determine realised benefits.

Evidence class: conceptual draft; primary-source key/distractor review pending (C15).

Original MCQ 16

Which law is most directly relevant to recognising specified forest-dwelling communities' forest rights?

A. Companies Act 2013
B. National Highways Act 1956
C. Special Economic Zones Act 2005
D. Scheduled Tribes and Other Traditional Forest Dwellers (Recognition of Forest Rights) Act 2006

Key: D. The 2006 Forest Rights Act provides the legal framework for recognising qualifying individual and community forest rights; application is conditional.

Evidence class: conceptual draft; primary-source key/distractor review pending (C16).

Original MCQ 17

Why does a road near a village not guarantee market integration?

A. Safe access points, transport services, costs and travel-time reliability still matter
B. Roads cannot carry agricultural goods
C. Only railways permit movement between districts
D. Road proximity always guarantees producer prices

Key: A. Connectivity must be usable and affordable, not merely visible on a map.

Evidence class: conceptual draft; primary-source key/distractor review pending (C17).

Original MCQ 18

What is the most defensible way to evaluate an announced industrial park?

A. Count projected jobs as realised jobs
B. Track operational firms, realised employment, wages, suppliers and environmental compliance
C. Assume all land allotments are producing output
D. Use only the value of memoranda of understanding

Key: B. Announcements and investment intentions must be separated from realised activity and employment.

Evidence class: conceptual draft; primary-source key/distractor review pending (C18).

Original MCQ 19

What is a major limitation of measuring water conservation only by tank desiltation volume?

A. It precisely measures household drinking-water access
B. It proves downstream flow increased
C. It does not establish storage recovery, actual deliveries or basin-wide net savings
D. It always proves recharge doubled

Key: C. A volumetric works metric is not equivalent to measured water-service or basin outcomes.

Evidence class: partially official-source-correlated; item-level distractor audit pending (K3).

Original MCQ 20

Which caution applies to Ramappa's 2026 UNESCO buffer-zone discussion?

A. The decision legally dissolved the protected site
B. The decision certified all proposed works as harmless
C. The decision concerned only visitor ticket prices
D. Reported progress toward extension is not proof of completed boundary modification

Key: D. The World Heritage Committee discussed further boundary-modification and impact-assessment processes, not an already completed expansion.

Evidence class: partially official-source-correlated; item-level distractor audit pending (K4).

Original MCQ 21

Which comparison of cotton and paddy is analytically sound?

A. Crop suitability depends on water, soils, pests, input cost, prices and local institutions
B. Paddy never needs irrigation
C. Cotton prices are fixed across all seasons
D. Both have identical labour and pest profiles

Key: A. Crop choice reflects ecological and market trade-offs; blanket state-wide recommendations are unreliable.

Evidence class: conceptual draft; primary-source key/distractor review pending (C21).

Original MCQ 22

Which is the clearest risk of treating every rainfall deficit as hydrological drought?

A. Meteorological drought is never measurable
B. Reservoir and groundwater responses may lag or differ from rainfall anomalies
C. Hydrological drought is identical to price inflation
D. All aquifers recharge instantly after one storm

Key: B. Rainfall, soil moisture and water storage respond over different timescales and must be diagnosed separately.

Evidence class: conceptual draft; primary-source key/distractor review pending (C22).

Original MCQ 23

Which indicator most directly tests equitable canal delivery?

A. Length of the main canal only
B. Number of planned distributaries
C. Measured head-reach and tail-end deliveries across seasons
D. Only the dam's design capacity

Key: C. Tail-end water delivery reveals distributional performance that design capacity alone cannot demonstrate.

Evidence class: conceptual draft; primary-source key/distractor review pending (C23).

Original MCQ 24

Which approach best evaluates a Telangana district's sex ratio trend?

A. Compare unrelated district boundaries without adjustment
B. Treat child sex ratio and overall sex ratio as identical
C. Use any online number without reference year
D. State age group, year, boundary and consistent source before comparison

Key: D. Sex-ratio definitions and changing district boundaries must be controlled for meaningful comparisons.

Evidence class: conceptual draft; primary-source key/distractor review pending (C24).

Original MCQ 25

What is a strong integrated regional-development metric?

A. District-wise durable employment, irrigation service and household income alongside environmental outcomes
B. Only Hyderabad's investment announcements
C. Only kilometres of highways sanctioned
D. Only the number of scheme beneficiaries reported without denominators

Key: A. A multidimensional outcome set captures regional distribution and sustainability rather than inputs or publicity.

Evidence class: conceptual draft; primary-source key/distractor review pending (C25).

Six original structured mains model answers — NOT official PYQs

Model Answer 1 — 20 marks: Critically assess Mission Kakatiya as a strategy for agricultural water security.

Introduction: Telangana's tank systems historically captured local monsoon runoff. Mission Kakatiya sought to strengthen this distributed irrigation asset; its success depends on restoring catchment-to-command functioning rather than merely excavating sediment.

Hydrological logic: Removing sediment can recover useful storage where siltation has genuinely reduced capacity. Restored feeder channels, sluices, bunds and surplus weirs determine whether rainfall actually reaches the tank, remains safely stored and is distributed to fields. Tank seepage may contribute to groundwater recharge and fisheries or other ecosystem services, but results vary by geology and season.

Agrarian benefits: More dependable protective irrigation can support crop establishment during dry spells, improve yield stability and reduce the need for costly private borewells. Village tanks may benefit small holdings more equitably than large capital-intensive systems, provided water rights and distribution arrangements do not favour only head-reach farmers.

Critical limitations: Desiltation volume is an output, not an outcome. Without catchment treatment and encroachment control, sediment quickly returns. Water quality and disposal of dredged material require care. A

tank restored in one basin does not necessarily create net new water: downstream effects must be considered. Benefits are also limited where changing climate and intensive cropping expand demand beyond sustainable supply.

Recommendations: Use pre/post bathymetric surveys, seasonal storage, groundwater levels, command-water delivery, farmer-level access and independent social audits. Connect tanks to watershed works, crop-water budgeting, community institutions and well monitoring.

Conclusion: The distinctive strength of Mission Kakatiya is its **decentralised water infrastructure**, but its success should be judged by **reliable and equitable water service**, not by restored-tank counts or excavation expenditure.

Model Answer 2 — 20 marks: Explain how Hyderabad-centered industrialisation has reshaped Telangana and suggest a balanced development model.

Introduction: Hyderabad's economic concentration reflects agglomeration advantages in IT, pharmaceuticals, services, education and transport; it also creates pronounced intra-state spatial disparities.

Mechanism of concentration: Skilled labour markets, suppliers, investors, research institutions, airport connectivity and business services create cumulative advantages. Pharmaceutical manufacturing and research, IT services and specialised industrial estates benefit from proximity to complementary activities. Real estate, logistics and household services expand in response.

Distributional consequences: High-value jobs coexist with informal employment, commuting burdens, air and water pollution and rising land costs. Firms outside Hyderabad may face weaker supplier ecosystems, training institutions and market access. Rural youth often migrate before district economies can absorb their skills. Traditional weaving and household industries struggle to convert cultural recognition into durable bargaining power or stable wages.

Strategy: District growth centres need reliable roads and rail freight access, serviced industrial land, power and water, vocational institutions tailored to local value chains, digital connectivity and transparent environmental compliance. Agriculture-linked food processing and textile design/marketing can connect local resource economies to higher value markets. Regional industrial policy should measure wages, women's employment, small-supplier contracts, effluent performance and job durability, not announced investments alone.

Governance and conclusion: Metropolitan planning should protect catchments and moderate land speculation while local governments build capacity. The state should use Hyderabad's agglomeration as a **platform for statewide value chains**, rather than accept a permanent single-city development model. Inclusion is demonstrated by productive regional jobs and environmental outcomes, not by gross investment promises.

Existing answer 1 requires reduction from its previously audited 258-word length; verify both inherited answers and do not mark R6 PASS.

Original mains answer 3: Analyse drought vulnerability in Telangana and propose a multi-layered response.

Introduction: Drought vulnerability in Telangana is shaped by variable monsoon timing, hard-rock groundwater systems, crop choices and unequal access to credit. Statewide rainfall averages can conceal serious mandal-level distress.

Diagnostic framework: Meteorological drought concerns deficient rainfall; agricultural drought concerns inadequate root-zone moisture; hydrological drought concerns declining streamflow, reservoir storage or groundwater. These may emerge at different times. A late onset delays sowing, while a dry spell during flowering may damage an established crop. Monitoring should combine rainfall anomalies, crop condition, soil moisture, well levels and tank storage.

Economic exposure: Smallholders and tenant cultivators may lack reliable irrigation or formal credit. Cotton and paddy face different input, water and price risks. Relief tied only to land ownership can overlook cultivators and agricultural workers. Procurement arrangements and local market access influence whether crop diversification is financially viable.

Policy response: Use crop-stage advisories, drought-tolerant seed where suitable, soil-moisture conservation, accountable protective irrigation and crop-specific contingency plans. Map aquifers, measure pumping and negotiate village water budgets. Expand timely insurance settlement, affordable credit and access for tenant farmers. District plans should publish transparent triggers and track delivery to vulnerable groups.

Limitations and conclusion: No single reservoir, crop or rainfall threshold can eliminate drought risk. The priority is locally differentiated water management coupled with income security and measurable resilience.

Draft count: 213 words; claim-level verification pending.

Original mains answer 4: Compare canal, tank and groundwater irrigation for equitable water security.

Introduction: Telangana uses canals, local tanks and wells to manage monsoon variability. These systems differ in scale, operating costs, governance and ecological effects; none is universally superior.

Canal systems: Gravity canals can serve substantial command areas, but performance depends on storage inflows, distributary maintenance and head–tail allocation. Planned hectares should not be confused with hectares receiving water in a particular season. Canal seepage and drainage need context-specific assessment.

Tank systems: Village tanks store local runoff and can support protective irrigation, livestock, fisheries and recharge. Mission Kakatiya describes restoration of feeders, bunds, sluices and weirs alongside desiltation. Yet excavation volume is not proof of improved service. Catchment erosion, encroachment and upstream–downstream effects influence outcomes.

Groundwater: Wells provide timely farm-level control but fractured hard-rock aquifers make extraction uneven and interdependent. Deeper pumping may disadvantage poorer neighbours and raise energy costs. Artificial recharge works only where geology and water quality permit.

Integrated governance: Combine measured surface-water deliveries with well monitoring, crop-water budgets and user participation. Track net and gross irrigated area separately, protect tail-end access and test whether smallholders actually receive dependable water. Community institutions need transparent allocation rules.

Conclusion: Sustainable irrigation is a coordinated water-service system. Success is measured by reliability, equity and aquifer trends, not simply new infrastructure or sanctioned command area.

Draft count: 211 words; claim-level verification pending.

Original mains answer 5: Examine the prospects and limits of Telangana's craft and tourism economies.

Introduction: Telangana's crafts and tourism link place-based cultural knowledge to livelihoods, but visitor numbers and brand recognition do not automatically generate equitable incomes.

Craft geography: Pochampally ikat, Gadwal and Narayanpet textiles demonstrate specialised weaving traditions. Production involves yarn procurement, household labour, design, traders and retail markets. Artisans can face working-capital constraints, volatile input prices and bargaining disadvantages. A geographical indication or marketing campaign should be evaluated through genuine producer earnings and continuity of skills.

Tourism circuits: Hyderabad's monuments, Warangal and Ramappa heritage, pilgrimage centres and natural landscapes can support accommodation, guides, transport, food services and craft sales. Yet local multiplier

effects depend on procurement links and employment quality. Excess traffic, waste and water demand can damage fragile sites.

Heritage safeguards: The 2026 UNESCO decision on Ramappa discusses reported progress toward a broader protected landscape and further assessment requirements. It does not demonstrate that a buffer-zone modification is already legally complete. Proposed construction requires careful heritage-impact evaluation rather than an assumption of unconditional permission.

Policy approach: Support producer cooperatives, design training, verified provenance, digital sales and fair payments. Improve last-mile transport, waste services and local guide skills while monitoring ecological carrying capacity and community participation.

Conclusion: A successful cultural economy preserves heritage while distributing measurable, durable income to resident workers and craft households.

Draft count: 212 words; claim-level verification pending.

Original mains answer 6: Discuss demographic and tribal-development challenges in Telangana.

Introduction: Telangana's development geography combines Hyderabad-centred migration with varied rural and forest-region populations. Demographic indicators must be interpreted using consistent boundaries and definitions.

Measurement: Census 2011 remains an important historical baseline, but subsequent district reorganisation complicates direct comparison. Population density is population divided by area; growth compares populations over a defined period. Overall and child sex ratios measure different age groups. Literacy comparisons must state their age base. New district estimates should not be presented as directly comparable with undivided older districts without a spatial crosswalk.

Urban and regional dynamics: Hyderabad attracts skilled and informal workers, while district towns differ in industrial opportunities and service capacity. A large working-age cohort creates only a potential demographic dividend. Education, health, transport, women's labour participation and durable jobs determine whether it is realised.

Tribal concerns: Forest and hill communities face distinct histories of land access, forest produce dependence, displacement and service gaps. Roads may improve health access while increasing resource pressure. Fifth Schedule protections, the 1996 PESA framework where applicable and the 2006 Forest Rights Act require careful implementation and community participation.

Governance: Publish comparable district statistics, support culturally appropriate schooling and health care, strengthen land-rights administration and evaluate project impacts on households.

Conclusion: Population policy must combine accurate measurement with spatial justice, rather than treating aggregate growth or infrastructure spending as evidence of inclusion.

Draft count: 222 words; claim-level verification pending.

Current affairs and source-status notes

The Government of Telangana reports Socio Economic Outlook 2026 on its official reports page. Use it as the primary source for the most recent state crop, industrial and demographic indicators; no statistical amount is invented in this revision. Source: https://www.telangana.gov.in/reports/

UNESCO 2026 Decision 48 COM 7B.11 deals with protection and assessment requirements for Ramappa landscape and planned work, rather than an assertion of completed upgrades. Source: https://whc.unesco.org/en/decisions/9068

Claim-level verification: identify table and issue date before any numeric value is used.

Directly source-correlated claims (partial R4 only)

- K1–K3: Telangana government's Mission Kakatiya programme description and its **historical 2014** 46,531-source enumeration: https://www.telangana.gov.in/mission-kakatiya/ . Neither a 2026 tank count nor independent outcome evaluation.
- K4: UNESCO 2026 World Heritage Committee Decision 48 COM 7B.11: https://whc.unesco.org/en/decisions/9068 . Buffer-zone expansion process discussed; not already completed.
- C01–C25: Editorial/conceptual question tags. Unless separately correlated above, **NOT independently claim-level verified**. Before R5 PASS, check all 25 keys, 75 incorrect options and explanations against direct primary or authoritative textbook evidence.

Newly source-correlated teaching claims (26 October 2026; partial R4/R5 only)

- **K5 / MCQ6 key B (conceptual):** CGWB's 2024 Maheshwaram–Shamshabad–Kothur aquifer management plan documents aquifer mapping and the need for geological and hydrological analysis. It supports the *approach* of mapping and budgets; it does **not** establish an exact safe yield for all Telangana aquifers. Source: https://cgwb.gov.in/cgwbpnm/public/publication-detail/1634 . Other MCQ6 distractors still require independent item-level review.
- **K6 / MCQ10 key (statutory distinction):** Special Economic Zones Act, 2005, sections 2(za), 3–4 distinguish proposal and legal notification. This supports the *SEZ legal category*, not the status of any named Telangana project. Source: https://www.indiacode.nic.in/indiacode/handle/123456789/2042?view_type=browse . Other MCQ10 distractors still require independent item-level review.
- **K1–K3 / MCQ5 key A (evaluation):** the official Mission Kakatiya programme description supports tank restoration mechanisms and stated objectives; the question's preference for *actual command delivery* is an analytical outcome criterion, not a documented impact finding. Distractor validation remains open.

Cycle96 source-register additions — bounded author-side consultation (30 October 2026)

- **T96-S1 — ICAR-CRIDA (27–31 January 2025 training, Hyderabad):** https://icar.gov.in/en/training-programme-farmers-sustainable-rainfed-farming-pathway-livelihood-security-under-scsp . Supports rainfed agronomy, farm water management and post-harvest topics, not measured Telangana-wide outcomes.
- **T96-S2 — Telangana Directorate of Economics and Statistics, functional areas:** https://ecostat.telangana.gov.in/functional_area_des.html . Identifies rainfall and crop area/production/yield series; no specific district figures extracted.
- **T96-S3 — Tamil Nadu Agricultural University dryland intercropping guidance:** https://www.agritech.tnau.ac.in/agriculture/agri_majorareas_dryland_agromeasures_intercropping.html . General agronomic examples, not automatically a Telangana recommendation.
- **T96-S4 — NRSC/ISRO authors in IMD MAUSAM, 2016, Agricultural drought: Assessment & monitoring:** https://mausamjournal.imd.gov.in/index.php/MAUSAM/article/view/1155 . Article abstract consulted for indicators and spatial monitoring; complete PDF not independently examined.
- **T96-S5 — CGWB Dynamic Ground Water Resources of Telangana, 2024, repository entry (issued 2025):** https://cgwb.gov.in/cgwbpnm/publication-detail/1541 . Indexed official report excerpt consulted; full PDF retrieval failed. No local assessment-unit result asserted.
- **T96-S6 — Ministry of Tribal Affairs Forest Rights Act overview:** https://tribal.nic.in/FRA.aspx . Rights categories and Gram Sabha roles; not a Telangana implementation audit.
- **T96-S7 — Ministry of Tribal Affairs FRA Act, Rules and Guidelines booklet:** https://tribal.nic.in/FRA/data/FRARulesBook.pdf . Indexed rule excerpt used for claim-process distinctions; full original PDF not examined.

MCQ coverage this cycle: C01–C03 each received an author-side check of its key and three incorrect alternatives (3 keys, 9 distractors). This is **not independent academic approval** and does not certify C04–C25. The conceptual sections and sources remain subject to claim-level R4 and R5 review.

Cycle97 source register — directly viewed institutional pages (30 October 2026)

- **T97-S1 — Suryapet District Industries Centre:** https://suryapet.telangana.gov.in/industries/ . Local cement-industry example; not a statewide capacity census.
- **T97-S2 — Telangana Industries and Commerce Department:** https://www.telangana.gov.in/departments/industries-and-commerce/ . Confirms sugar industry within department remit; not proof of mill operation.
- **T97-S3 — Invest Telangana Life Sciences:** https://invest.telangana.gov.in/sectors/life-sciences/ . Government promotional cluster overview; company counts and investment claims not independently audited.
- **T97-S4 — Telangana Next-Gen Life Sciences Policy 2026–2030:** https://invest.telangana.gov.in/policy-life-sciences/ . Green Pharma City policy intentions; not proof of completed facilities.
- **T97-S5 — UNESCO Ramappa World Heritage property:** https://whc.unesco.org/en/list/1570 . Temple's cultural and irrigation landscape, property description and heritage assessment requirements.
- **T97-S6 — UNESCO Decision 47 COM 8B.38 (2025):** https://whc.unesco.org/en/decisions/8921/ . Approved property-boundary change; referred wider buffer-zone proposal back.
- **T97-S7 — UNESCO 2026 state-of-conservation decision:** https://whc.unesco.org/fr/soc/4906 . 48 COM 7B.11; review and impact-assessment requirements; French official text viewed, English original not independently checked in this cycle.
- **T97-S8 — Ministry of Textiles Handicrafts, Pochampally Ikat:** https://handicrafts.nic.in/crafts/All_Crafts/Craft_Categories/Textile/Other_Textiles_Based/ikkat/IkkatWebPage.html . Resist-dyed yarn production process.
- **T97-S9 — Telangana Tourism Arts and Crafts:** https://www.tourism.telangana.gov.in/page/arts-crafts . Named regional crafts; promotional description, not artisan earnings data.
- **T97-S10 — Hyderabad district Handicrafts:** https://hyderabad.telangana.gov.in/handicraft/ . Dokra lost-wax process and regional craft description.
- **T97-S11 — NRIDA PMGSY Core Network:** https://www.pmgsy.nic.in/core-network . Basic all-weather access to habitations and market centres.
- **T97-S12 — NRIDA PMGSY FAQ:** https://pmgsy.nic.in/frequently-asked-questions-pradhan-mantri-gram-sadak-yojana-pmgsy . Habitation and all-weather-road definitions; not Telangana outcome data.
- **T97-S13 — South Central Railway profile:** https://scr.indianrailways.gov.in/ministry/about-us . 1 June 2026 divisional reorganisation; historical zone totals need boundary caution.
- **T97-S14 — Telangana State Profile:** https://www.telangana.gov.in/about/state-profile/ . Census 2011 demographic values and distinct denominators; not 2026 population estimates.
- **T97-S15 — Telangana DES Telangana at a Glance:** https://www.ecostat.telangana.gov.in/telangana_glance.html . Exact 2011 population and literacy/sex-ratio tables.

Scope: seven core concepts (§§7, 8, 10, 11, 12, 13, 15) expanded in place; sources support bounded institutional or definitional claims, not an independent full R4 claim audit. No MCQ or mains keys were changed, no archival document consultation is claimed, and no official PYQs were invented. Post-edit PDF render, actual artifact download and browser accessibility are pending separate verification.

Publication and academic QA blockers

- R1: direct original official TGPSC syllabus clause-by-clause comparison pending.
- R2: consolidate repeated points in original narrative and prior six-section repair, then editorial contradiction review.
- R3: four core concepts (§§4,5,6,9) expanded with worked mechanisms and source caveats; the seven remaining shallow sections have now been expanded in place; qualitative depth and editorial nonduplication still require independent review. Automated word counts are a diagnostic, not a pass criterion.
- R4: claim-level evidence register incomplete; dated statistics require original tables and administrative scope.
- R5: 25 original explained draft MCQs written; ALL 25 key/distractor sets require complete source verification and discrimination review.
- R6: six model answers assembled, four new drafts within 200–250 words; two inherited answers require recheck, first previously exceeded 250 words.
- R7: SVG diagrams and map accuracy checks not completed; no visual claimed.
- R8: Cycle96 integrated PDF was downloaded and verified; this Cycle97 source edit requires a NEW synchronized CI PDF and fresh artifact CRC/SHA/75-topic/link QA. Full-resolution student usability remains outstanding; legacy original PDF remains untouched.
- R9: NOT STARTED; zero external academic approvals.
